Setting up your proxy

WRKSNET • PROXY SETUP GUIDE

iPhone, Android, Windows. On iPhone you can be running in under a minute.

What you have bought

A static residential IP in the country you chose, yours for one month. It is not shared with anyone else and it does not rotate, so the same IP stays with you for the whole period.

It works over both **SOCKS5** and **HTTP**, on the same port. That matters, because it means an iPhone can use it straight from Settings with no app at all.

Your four details

Every method in this guide uses the same four values, and nothing else:

YOUR PROXY	
IP address	**123.45.67.89**
Port	**40000**
Username	**yourusername**
Password	**yourpassword**

Example values. Yours are in the message the bot sent when your order completed.

If you need them again, open **Our Services** → **Proxies** → **Manage Proxies**.

Method 1 — iPhone, with no app

The quickest way to get going. It applies while you are on Wi-Fi.

Settings → **Wi-Fi** → **the (i) button** → **Configure Proxy** → **Manual**

HTTP PROXY		
Off	**Manual**	Auto
Server		**123.45.67.89**
Port		**40000**
Authentication		**ON**
Username		**yourusername**
Password		**yourpassword**

What the screen looks like once filled in.

Tap the small **i** in a circle next to the Wi-Fi network you are connected to, then scroll right to the bottom of that screen to find **Configure Proxy**.

Set it to **Manual**, turn **Authentication** on so the username and password fields appear, fill in your four values, and tap **Save** in the top corner.

Then search “what is my IP” in Safari. You should see your proxy's IP rather than your own.

To stop using it, come back to the same screen and set **Configure Proxy** to **Off**.

Three things worth knowing

- It applies on Wi-Fi only. iPhone has no way to send mobile data through a proxy.
- The setting is saved against that one Wi-Fi network, so you will set it again on a different network.

- Safari and most apps follow it automatically, but a few ignore proxy settings and connect directly anyway. If you need every app covered without exception, use Method 2.

Method 2 — iPhone, using Potatso

Use this if you need mobile data covered as well, or you want every app routed with no exceptions. Install **Potatso** from the App Store, or any other SOCKS5 proxy client, and add a new server.

ADD SERVER	
Type	**SOCKS5**
Address / Host	**123.45.67.89**
Port	**40000**
Username	**yourusername**
Password	**yourpassword**

The field names vary slightly between apps, the four values do not.

Choose **SOCKS5** as the type. Some apps call the first field Address, others Host or Server — they all mean your IP.

When you connect, the app will ask to install a **VPN profile** on your iPhone. That is normal and it is required, because iOS only lets apps route traffic that way. It is not a separate VPN service and it does not cost anything.

Once connected it covers both Wi-Fi and mobile data, and every app without exception.

If the connection drops after a while, open the app and reconnect. SOCKS connections are not as persistent as a full VPN.

Method 3 — Android

Android needs an app. Its built-in Wi-Fi proxy settings cannot be used, and it is worth seeing why so you do not waste time there:

WI-FI PROXY (DO NOT USE)	
Proxy hostname	**123.45.67.89**
Proxy port	**40000**
Bypass list	—
Username	**no such field**
Password	**no such field**

Android's own proxy screen has nowhere to put your username and password.

Your proxy needs a username and password, and Android's Wi-Fi proxy screen simply has no fields for them. Entering just the hostname and port will not connect.

So on Android, install a SOCKS5 proxy app from the Play Store and add a server with your four values, exactly as in Method 2:

ADD SERVER	
Type	**SOCKS5**
Server	**123.45.67.89**
Port	**40000**
Username	**yourusername**
Password	**yourpassword**

Method 4 — Windows

For browsing, a proxy extension in Chrome or Firefox is the simplest route, because you can switch the proxy on and off per site. Windows' own proxy settings handle HTTP but not SOCKS5.

PROXY SETTINGS	
Title	**WrksNet proxy**
Proxy type	**SOCKS5**
Host / IP	**123.45.67.89**
Port	**40000**
Username	**yourusername**
Password	**yourpassword**

A browser proxy extension's add-proxy form.

Install a proxy extension such as **FoxyProxy**, add a new proxy, and fill in the same four values with the type set to **SOCKS5**.

Give it a title you will recognise, then switch it on from the extension's icon in the toolbar whenever you need it.

Only that browser's traffic goes through the proxy, which is usually what you want on a desktop — everything else on the machine carries on as normal.

Checking it is working

Search “what is my IP” in whichever browser you set up. If it shows your proxy's IP, you are connected. If it shows your normal IP, the proxy is not being used. Check the port and the password first, as those are the two people usually mistype.

Renewing

We message you two days before your proxy expires, with a renew button on the message. Renewing keeps the same IP.

If it lapses before you renew, the IP goes back to the pool and we cannot promise you will get the same one again, so renewing early is always safer. You can renew at any time under **Our Services** → **Proxies** → **Manage Proxies**.

Swapping your IP

If your IP stops working for the site you need, you can swap it for a different one in the same country. Open **Our Services** → **Proxies** → **Manage Proxies** and choose Swap IP.

If you need a specific US state

Our proxies are selected by country rather than by state, so there is no state option in the menu. If you need a particular state, tap **Contact Support** and tell us which one. We arrange those by hand.

If something is not working

Check the port and password first. Then make sure you are on Wi-Fi if you used Method 1. If it still will not connect, tap **Contact Support** and send us your IP, and we will check it from our side.

> **The short version**
>
> iPhone on Wi-Fi: Settings → Wi-Fi → the (i) beside your network → Configure Proxy → Manual, then your IP, port, username and password. Nothing to install. For mobile data, for Android, or to cover every app without exception, use a SOCKS5 app with the same four details. On Windows, a browser proxy extension.
