Setting up your proxy

WRKSNET • PROXY SETUP GUIDE

On iPhone you can be running in under a minute, with nothing to install.

What you have bought

A static residential IP in the country you chose, yours for one month. It is not shared with anyone else and it does not rotate, so the same IP stays with you for the whole period.

It works over both **SOCKS5** and **HTTP**, on the same port. That matters, because it means an iPhone can use it straight from Settings with no app at all.

Finding your details

Your four details are the IP, the port, the username and the password. They are in the message the bot sent you when your order completed.

If you need them again, open **Our Services** → **Proxies** → **Manage Proxies**.

iPhone, with no app

This is the quickest way to get going. It applies while you are on Wi-Fi.

1. Open **Settings** → **Wi-Fi**
2. Tap the small **i** beside the network you are connected to
3. Scroll to the bottom and tap **Configure Proxy**
4. Choose **Manual**
5. Fill in the fields as shown below, then tap **Save**

What iPhone asks for	What to enter
Server	The IP from your order message
Port	The port from your order message
Authentication	Turn it on
Username	The username from your order message
Password	The password from your order message

That is everything. To check it worked, search “what is my IP” in Safari. You should see your proxy's IP rather than your own.

To stop using it, go back to the same screen and set **Configure Proxy** to **Off**.

Three things worth knowing

- It applies on Wi-Fi only. iPhone has no way to send mobile data through a proxy.
- The setting is saved against that one Wi-Fi network, so you will set it again on a different network.
- Safari and most apps follow it automatically, but a few ignore proxy settings and connect directly anyway. If you need every app covered without exception, use the app method below.

iPhone, using an app

Use this if you need mobile data covered as well, or you want every app routed with no exceptions.

Install a SOCKS5 proxy client from the App Store, add a new SOCKS5 server, and enter your IP, port, username and password. The app will ask to install a VPN profile on your iPhone. That is normal and it is required, because iOS only lets apps route traffic that way. Once connected it covers both Wi-Fi and mobile data.

Android

Android's Wi-Fi proxy settings have nowhere to enter a username and password, so your details cannot go there. On Android you will need a SOCKS5 proxy app from the Play Store. Add a SOCKS5 server with your IP, port, username and password, then connect.

Windows

For browsing, a proxy extension in Chrome or Firefox is the simplest route. Add a SOCKS5 proxy with your four details and switch it on. Windows' own proxy settings handle HTTP but not SOCKS5, so an extension gives you more control and lets you turn the proxy on and off per site.

Checking it is working

Search “what is my IP” in whichever browser you set up. If it shows your proxy's IP, you are connected. If it shows your normal IP, the proxy is not being used. Check the port and the password first, as those are the two people usually mistype.

Renewing

We message you two days before your proxy expires, with a renew button on the message. Renewing keeps the same IP.

If it lapses before you renew, the IP goes back to the pool and we cannot promise you will get the same one again, so renewing early is always safer. You can renew at any time under **Our Services** → **Proxies** → **Manage Proxies**.

Swapping your IP

If your IP stops working for the site you need, you can swap it for a different one in the same country. Open **Our Services** → **Proxies** → **Manage Proxies** and choose Swap IP.

If you need a specific US state

Our proxies are selected by country rather than by state, so there is no state option in the menu. If you need a particular state, tap **Contact Support** and tell us which one. We arrange those by hand.

If something is not working

Check the port and password first. Then make sure you are on Wi-Fi if you used the iPhone method with no app. If it still will not connect, tap **Contact Support** and send us your IP, and we will check it from our side.

> **The short version**
>
> iPhone on Wi-Fi: Settings → Wi-Fi → the i beside your network → Configure Proxy → Manual, then your IP, port, username and password. Nothing to install. For mobile data, for Android, or to cover every app without exception, use a SOCKS5 app with the same four details.
